Frequently Asked Questions (FAQ)

Q1: What are the key differences between feedback and feedforward control in bioprocesses?

A1: Feedback control uses measurements of the process output to adjust the control input. It's reactive, correcting deviations after they occur. Feedforward control uses measurements of disturbances affecting the process to predict and compensate for their effects **before** they impact the output. Ideally, a combination of both strategies is used for optimal control.

Q2: How do I choose the right sensor for my bioprocess?

A2: Sensor selection depends on the specific parameter you need to measure (pH, temperature, dissolved oxygen, etc.), the accuracy required, the process environment (sterile, harsh conditions), and the cost. Consult the solution manual for guidance on sensor characteristics and selection criteria.
